AE4803

Aircraft Propulsion Performance

- Performance parameters
 - relevant to making a “good” propulsion system
 - **Specific Thrust (ST)**

$$\equiv \frac{\tau}{\dot{m}_a}$$

- **Specific Fuel Consumption (SFC)**

$$TSFC \equiv \frac{\dot{m}_f}{\tau} = \frac{u}{\eta_o \Delta h_R}$$

- engine efficiencies, η

overall

thermal (cycle)

propulsive

$$\eta_o \equiv \frac{\tau u}{\dot{m}_f \Delta h_R}$$

$$\eta_{th} \equiv \frac{\Delta KE}{\dot{m}_f \Delta h_R}$$

$$\eta_p \equiv \frac{\tau u}{\Delta \dot{KE}}$$

$$\eta_o = \eta_{th} \eta_p$$

T-s (Mollier) Diagrams

- Often drawing an engine cycle on a T-s state diagram is very helpful to understanding performance

- isothermal process?
- isentropic process?
- isobaric process?
- isochoric (isodensity) process?

Note: p lines diverge to the right

AE4803

Component Adiabatic Efficiency

- $\eta \equiv$ ratio of enthalpy change across device and enthalpy change if device was: 1) reversible, 2) adiabatic, 3) same inlet state, 4) same exit pressure AND must be < 1
 - e.g. for compressor,

$$\eta_c = \frac{h_{o_{3s}} - h_{o_2}}{h_{o_3} - h_{o_2}} \quad \text{OR} \quad \eta_c = \frac{h_{o_3} - h_{o_2}}{h_{o_{3s}} - h_{o_2}} = \frac{\dot{W}_{c,ideal}}{\dot{W}_{c,actual}} < 1$$

The diagram shows a T-s plot for a compressor. The vertical axis is labeled h, T and the horizontal axis is labeled s . Two solid curves represent isobaric processes at pressures p_{o_2} and p_{o_3} . A dashed curve represents an isentropic process. Points o_2 , o_3 , and o_{3s} are marked on the diagram.

AE4803

Single-point Design/On-design Analysis

- **First** - understand specific thrust and fuel burn/SFC performance for **varying engine designs**
 - changing *design values*:
 - BPR (β) • OPR (Pr_o) • FPR (Pr_f) • T4
 - most other values constrained, e.g., fuel heating value ($\sim 43\text{MJ/kg}_{\text{fuel}}$ for standard jet fuels), and component (polytropic) efficiencies
 - changing flight conditions
 - altitude: T_a, p_a (or T_∞, p_∞)
 - flight Mach # M (or flight velocity u)
 - cycle design typically focused on point **where most efficient operation is desired** (usually cruise)

AE4803

Improved Engine Performance

- Generally want to increase overall efficiency

$$\eta_o = \eta_{th} \eta_p$$

1. How to improve thermal (cycle) efficiency?
2. How to improve propulsive efficiency?

Airbreathing Propulsion Review -8

AE4803

Gas Turbine Thermal (Cycle) Efficiency

- Cycle pressure ratio is the dominant influence
 - $\eta_{th} \uparrow$ with Pr
- With irreversible (real) turbomachinery, $\eta_{th} = f(T_{max})$
 - $\eta_{th} \uparrow$ with T_{max}

AE4803

Ramjet Performance

$\gamma = 1.3-1.4$
 $T_a = 220K$
 $HV = 45MJ/kg$
 $\eta_D = 0.92 \& ram$
 recovery
 $\eta_B = 0.99$
 $p_{rb} = 0.98$
 $\eta_N = 0.95$

AE4803

Single-point Design/On-design Analysis

- **Second** - select *design point*(s) to **size** the engine mass flow or area to produce required thrust
 - size usually set for **most demanding point in terms of thrust**
 - typically takeoff (or dash for fighter aircraft)
 - mass flow rate dependence on flow area also impacted by flow conditions
 - e.g., for tpg/cpg

$$\dot{m} = A \frac{P_o}{\sqrt{RT_o}} f(\gamma, M)$$

Airbreathing Propulsion Review -12

AE4803

Single-point Design/On-design Analysis

- So engine sizing done in terms of **corrected mass flow rates**

$$\dot{m}_c = \dot{m} \frac{\sqrt{T_o/T_{ref}}}{p_o/p_{ref}} \quad \text{e.g., } T_{ref}=288.2\text{K}(518.7\text{R})$$
$$p_{ref}=101.3\text{kPa} (14.7\text{psi})$$

- inlet size constrained by Mach number and choking considerations
- flow areas of fan, compressors, turbines, combustor also must handle required mass flow rate within velocity/Mach number constraints

Course Focus

- The issues raised so far
 - single-point cycle design and performance were the focus of AE 4451
- So what will be the focus of this course?
 1. Design of jet engine components
 2. Off-design engine performance
 3. “Unconventional” cycles for hypersonic flight, increased efficiency and reduced emissions

Design of Jet Engine Components

- Want to design efficient and “robust” engine components
 - turbomachinery: compressors, fans, turbines
 - blade geometry (e.g., angles), rpm, flowrate,...
 - combustors
 - geometry, fuel atomization, air staging and liner cooling ...
- Also want to know how these components will operate when we go an “off-design” condition

AE4803

Unconventional Cycles

- Conventional jet engines based on Brayton cycle
 - assumes constant pressure heat addition
- Can we do better, i.e., higher η_{th} ?
 - yes!, constant volume combustion will result in less entropy rise than constant pressure for the same temperature rise

Airbreathing Propulsion Review -16

AE4803

Unconventional Cycles

- To achieve high supersonic (hypersonic) flight speeds with airbreathing engines need supersonic internal flow: **scramjets**
 - what are the unique design issues for scramjet engines?
- To reduce emissions and improve efficiency, **electric propulsion** can be helpful
 - what are the issues for using electrical energy to drive motors that turn propulsors (e.g., propellers or fans)?
